Online Fair Division with Subsidy

Fair Division of Indivisible Goods

Fairly divide m indivisible goods among n agents.

	item a	item b	item c
agent 1	0.75	0.75	1
agent 2	1	1	0.5

For now, assume **additive** valuations,
where agent i 's value for bundle X_i is $v_i(X_i) = \sum_{g \in X_i} v_{i,g}$

Envy-Freeness

Allocation is **envy-free** (EF) if $v_i(X_i) \geq v_i(X_j)$ for all i, j .

	item a	item b	item c
agent 1	0.75	0.75	1
agent 2	1	1	0.5

 envy

$v_2(X_2) = 1$ $v_2(X_1) = 1.5$

Envy-free allocations might **not** exist.

Fair Division with Subsidy

Allocation X with **subsidy vector** $p = (p_1, \dots, p_n)$ is **envy-free** if $v_i(X_i) + p_i \geq v_i(X_j) + p_j$ for all i, j .

	item a	item b	item c	subsidy
agent 1	0.75	0.75	1	0
agent 2	1	1	0.5	0.5

$$v_2(X_2) + p_2 = 1.5 \quad v_2(X_1) + p_1 = 1.5$$

This allocation is **envy-free** with subsidy!

Fair Division with Subsidy

Allocation X with **subsidy vector** $p = (p_1, \dots, p_n)$ is **envy-free** if $v_i(X_i) + p_i \geq v_i(X_j) + p_j$ for all i, j .

Very active area of research.

Focus on minimizing **total subsidy** $\sum_{i \in [n]} p_i$.

Fair Division with Subsidy

Allocation X with **subsidy vector** $p = (p_1, \dots, p_n)$ is **envy-free** if $v_i(X_i) + p_i \geq v_i(X_j) + p_j$ for all i, j .

When does X admit p making it **envy-free**?

Theorem: X is **envy-freeable** iff X is **locally efficient**: there exists *no* permutation $\pi : [n] \rightarrow [n]$ with

$$\sum_{i \in [n]} v_i(X_{\pi(i)}) > \sum_{i \in [n]} v_i(X_i).$$

Online Fair Division with Subsidy

Online Fair Division

Items are arriving **online**, while agents are **offline**.

new item arrives

	item a	item b	item c	item d
agent 1	0.75	0.75	1	1
agent 2	1	1	0.5	0.5

We **can't modify** past allocations.
Future items are **unknown**.

Online Fair Division

Items are arriving **online**, while agents are **offline**.

Very active area of research.
Strong **impossibilities**: e.g., cannot achieve
envy-freeness up to some good (EF1).

Online Fair Division with Subsidy

Starting Point

Theorem: For **additive** valuations, there is an **online** algorithm that is **envy-free** with **total subsidy** $\leq m(n - 1)$.

Proof: Assign each item to agent who values it most.
maximizes welfare \Rightarrow **local efficiency** \Rightarrow **envy-freeability**

	item 1	...	item m	subsidy	
agent 1	1	1	1	0	} total subsidy $\geq m(n - 1)$
agent 2	$1 - \epsilon$	$1 - \epsilon$	$1 - \epsilon$	$m(1 - \epsilon)$	
\vdots	$1 - \epsilon$	$1 - \epsilon$	$1 - \epsilon$	$m(1 - \epsilon)$	
agent n	$1 - \epsilon$	$1 - \epsilon$	$1 - \epsilon$	$m(1 - \epsilon)$	

Research Direction

Theorem: For **additive** valuations, there is an **online** algorithm that is **envy-free** with **total subsidy** $\leq m(n - 1)$.

Question 1: Can we go beyond **additive** valuations?

Question 2: Is it possible to use **small subsidy** that does not grow with the number of items m ?

Q1: Beyond Additive Valuations

	Can EF be achieved online ? (Our Work)	Can EF be achieved offline ? (Prior Work)
Additive	YES	YES
SPLC	YES	YES
Binary Submodular	NO	YES
Binary Supermodular	NO	YES
Budget Additive	NO	YES
General Monotone	NO	YES

Strong **online vs. offline** separation.
Three **incomparable** impossibilities for **highly structured** classes.

Q2: Small Subsidy

	Can we get EF with small subsidy ?	(Mostly) tight online subsidy bounds	Offline subsidy bounds (Prior Work)
Additive	NO	$m(n - 1)$	$n - 1$
Rank-One	YES	$n(n + 1)/2 - 1$	$n - 1$
Restricted Additive	YES	$n(n - 1)/2$	$n - 1$
k -Demand	YES	$k(n - 1)$	$n - 1$
k -Valued	YES	$\leq n^2 k^n$	$n - 1$
Identical Monotone	YES	$n - 1$	$n - 1$

Offline subsidy for **additive** is $n - 1$.

Online subsidy is $\Omega(n^2)$ even for **structured** subclasses of **additive**.

Q2: Small Subsidy

Thm: There is *no* **online** algorithm that achieves **envy-freeness** with **total subsidy** $< m(n - 1)$ for **additive** valuations.

	item 1	item 2	item 3	...	subsidy
agent 1	$1 - \epsilon + 2\delta$	$1 - \epsilon + 4\delta$	$1 - \epsilon + 8\delta$...	0
agent 2	$1 - \epsilon + \delta$	$1 - \epsilon + 2\delta$	$1 - \epsilon + 4\delta$...	$\approx m$
⋮	$1 - \epsilon + \delta$	$1 - \epsilon + 2\delta$	$1 - \epsilon + 4\delta$...	$\approx m$
agent n	$1 - \epsilon + \delta$	$1 - \epsilon + 2\delta$	$1 - \epsilon + 4\delta$...	$\approx m$

Local efficiency at every step forces **all items** to agent 1.

Connection to Envy Minimization

We focus on achieving **envy-freeness** with **small subsidy**.

Related line of work studies **online envy minimization**:
maintain allocation with $v_i(X_j) - v_i(X_i) \leq E$ for small E .

[Aleksandrov, Aziz, Gaspers, Walsh, IJCAI 2015] [Benade, Kazachkov, Procaccia, Psomas, Zeng, OR 2024]
[Halpern, Psomas, Verma, Xie, EC 2025] [Dang, Halpern, Makur, Psomas, Singh, Verma, 2026]

Lemma: Any online algorithm that
maintains **local efficiency** and has **envy bounded** by E
can yield **envy-freeness** with **total subsidy** $\leq E \cdot n(n - 1)$.

Local efficiency is the source of hardness in our setting.

Summary

Question 1: Is it possible to maintain **envy-freeability online** beyond **additive** valuations?

Additive	YES
SPLC	YES
Binary Submodular	NO
Binary Supermodular	NO
Budget Additive	NO

Question 2: Is it possible to achieve **envy-freeness online** with **small subsidy** independent of m ?

Additive	NO	$m(n - 1)$
Rank-One	YES	$n(n + 1)/2 - 1$
Restricted Additive	YES	$n(n - 1)/2$
k -Demand	YES	$k(n - 1)$
k -Valued	YES	$\leq n^2 k^n$ (?)
Identical Monotone	YES	$n - 1$
